Eruption Time Estimation of Permanent 1st Molar, Central & Lateral Incisors in 5.5 - 10 Years Age Children at Al Ramadi City / Iraq

Mohammed Khudher Abdulhammed. (1) Lamia Ibrahim Sood. (2) Zena Hekmat AL_Taee. (3)

Introduction:
Eruption is a process of biological maturation in which the tooth is axially moved from there developmental position within the jaw toward their functional position in the occlusal plan [1].

Abstract
The Parents consider tooth eruption as an important thing in the child's life development, and they have often showed their concern about the timing of eruption of teeth. The purpose of this study were to Estimate the average age for eruption time of Permanent 1st molar, central & lateral incisors in upper & lower Jaw (right & left) in both gender and to Compare the eruption time of these teeth between upper & lower Jaw. right & left side, male &female. This study was conducted at Al Ramadi City / Iraq, where the sample was consisted of “786” children (391 male & 395 female) of age 5.5 years to 10 years were they taken randomly from various schools. Eruption of various permanent teeth (1st Molar, Central & Lateral Incisors teeth) were noted in both jaws and both sides. In our study we found that the permanent 1st molars were the first permanent tooth that erupts in all children at the age between 5.87 – 7.96 years on both jaws and on both right and left sides with the mean age of eruption at 6.57 ± 0.55 years in lower jaw and 6.62 ± 0.53 years in upper jaw. In addition to that our study showed that the next permanent teeth to erupt were central incisors which erupt at the age between 6.14 – 8.93 years on both jaws and on both right and left sides with the mean age of eruption at 7.23 ± 0.61 years in lower jaw and 6.29 ± 0.57 years in upper jaw. Finally, the eruption of permanent lateral incisors were at the age between 7.66 – 9.93 years on both jaws and on both right and left sides with the mean age of eruption at 8.89 ± 0.56 years in lower jaw and 8.93 ± 0.55 years in upper jaw. The teeth erupted in female earlier than male and in the lower Jaw than upper Jaw. In the most cases the right lower teeth erupted earlier than the other quadrant of both jaws. In general, we found that there was delay in the time of eruption of nearly all the teeth that were included in this study.

Key words
Eruption, Ramadi city, Permanent teeth

124
Parents regard tooth eruption as an essential event in the child’s development and they have often showed their interest in the tooth eruption timing. However the literature suggests that tooth emergence standards should be derived from the population they are to be applied because emergence related factors may vary considerably in both dentition and BMI [2]. Similarly, diagnosis and treatment planning in pediatric dentistry, orthodontics and Community Medicine for monitoring the growth of children require adequate knowledge of permanent tooth emergence timing [3].

Furthermore, in the diagnosis of certain growth disturbances, and in forensic dentistry to estimate the chronological age of children with unknown birth records; tooth emergence information used to supplement Maturation indicator [2-5]. Assessment of dental age can be done through radio-graphical and clinical visualization of teeth eruption; crowns and roots of teeth formation and calcification can be followed by radio-graphical visualizations of teeth eruption [6]. Gonzales et al., m described that the teeth may give reliable information as to the age in childhood and youth. Eruptions of permanent teeth begin at 6 year and all the permanent teeth except the third molars or wisdom teeth erupt by twelve to fourteen years [7].

Eruption times and emergence of permanent teeth be affected by variables like genetic and hormonal factors geographical, ethnic, gender, as well as economic status parameters have been reported [2][8-13].

At Al Ramadi City this study was done to Estimate & find out the average age for eruption time of Permanent 1st molar, central & lateral incisors in upper & lower Jaw (right & left) in both gender, and to Compare the eruption time of these teeth between upper & lower Jaw (right & left side), and male & female, no previous Iraqi studies were done in this subject, so it is intended to implement this research.

**Materials and method:**
The objectives and methodology were explained to all participants and Ethical consent was obtained from their parents in addition to agreement of Iraqi Ministry of Education \ Directorate of Education in AL Ramadi City and school officers before starting the examination of the children.

The study was conducted at Al Ramadi City / Iraq during the period of September 2013 to June 2014, 786 children (391 male & 395 female) of age 5.5 years to 10 years were included in this study which were taken randomly from various schools. Eruption of various permanent teeth (1st Molar, Central & Lateral Incisors teeth) were examined in both jaws and both sides.

The teeth were examined visually in good light using probe, spatula and mouth mirror for eruption. The examination takes place teeth either by good daylight or by using a torch having a very fine focusing of light. A tooth was considered erupted, if it has pierced through gums and UN erupted if not present in oral cavity [5]. Excluded from the sample children with palate malformation, those with cleft lip and palate, and those with obvious asymmetry or exposed to trauma in previous years and those who had dental orthodontics.

The personal information about each child such as age, educational level, date of birth, place of birth, and family name was recorded on the especially designed form taken from their personal files in the school record.

**Statistical Analysis:**
All the Data analysis was produced using the Statistical Package for Social Science version SPSS 22. Descriptive statistics were tabulated including mean age, range and S.D. for eruption of each tooth in the upper and lower jaw and also for right and left sides of the same jaw.

Analysis of variance was used to determine whether significant differences existed between the Male and female; upper & lower Jaws; Right & left side.

**Results:**
The total sample of this study was divided according to their gender into 391 (49.75%) male and 395 (50.25 %) female with age 5.5 -10 years (Table 1).
In some patients, the permanent tooth still unerupted in some sides in spite of the same contralateral tooth in the other side was erupted this may be due to normal variations which in agreement with the finding of Profit et al., 2013 who mention that a 6-month difference in the date of eruption of a tooth is considered normal. So the number of erupted right upper molar was (89) while the number of erupted left upper molar was (88) and so on for the remaining teeth.

It was found that in most cases the permanent teeth erupted earlier in the females than males and that the eruption of teeth was earlier in mandible (lower jaw) than in maxilla (upper jaw). These findings were compatible with Dahiya et al. findings where they found that female and mandible eruption occur earlier. However, it was incompatible with Kuldeep Singh et al. and Illieva et al. findings where they found that the 1st molar showed no significant difference in eruption and person sex as well as no difference in eruption in two jaws, where it may be attributed to race or environment effect or life style and social economy.

In our study, we found that the permanent 1st molars were the first permanent teeth that erupt in all children at the age between 5.87 – 7.96 years on both jaws and on both right and left sides with the mean age of eruption at 6.57 ± 0.55 years in lower jaw and 6.62 ± 0.53 years in upper jaw (table 2).

This finding was in agreement with finding of Kuldeep et al. where he found the eruption of 1st molar at age between 5.81 to 7.91 years and also in agreement with Grewal who in his study found that first permanent teeth to erupt was 1st molar and erupts at the age between 6 to 7 years.

In addition to that our study showed that the next permanent teeth to erupt were central incisors which erupt at the age between 6.14 – 8.93 years on both jaws and on both right and left sides with the mean age of eruption at 7.23 ± 0.61 years in lower jaw and 6.29 ± 0.57 years in upper jaw (table 3).

This finding was nearly in disagreement with finding of Dahiya et al. where found the eruption of permanent central incisors between age 6.11 to 8.60 years, also in disagreement with Kuldeep et al. where he found the eruption of central incisors at age between 6.08 to 8.71 years this disagreement may be due to the race or the effect of environment or life style and social economy.

Finally, the eruption of permanent lateral incisors were at the age between 7.66 – 9.93 years on both jaws and on both right and left sides with the mean age of eruption at 8.89 ± 0.56 years in lower jaw and 8.93 ± 0.55 years in upper jaw (table 4).

This finding was nearly in disagreement with finding of Dahiya et al. where found the eruption of permanent lateral incisors between age 7.56 to 9.86 years, also in disagreement with Grewal where he found the eruption of lateral incisors at age between 8 to 9 years this disagreement may be due to the race or the effect of environment or life style and social economy.

Within the range of 4.5 to 14.0 years. They found no difference between eruption ages of homologous permanent teeth on the left and the right side of the same jaw.

Conclusion:
- The teeth erupted in female earlier than male.
- In the lower Jaw erupted earlier than upper Jaw.
- In the most cases the right lower teeth erupted earlier than the other quadrant of both jaws.
- In general, we found that there were delay in the time of eruption of nearly all the teeth that were included in this study.
